# Raspberry Pi Dual Path Monitoring for Honeywell Vista Security Systems

#### **Overview**

This document describes a fun and useful "home-baked" Raspberry Pi project and who doesn't like a nice slice of pie? Some may perhaps be derisive and just "blow a raspberry", but if you take the time to read this document, it may prove to be of interest.

A security system is said to be "dual path enabled" when it has *both* IP (Internet Protocol) and cellular communication capability. Should Internet connectivity be lost, the security system can still send alerts, via a cellular communication network, typically to one or more cellular ("mobile") telephones. In this document, the acronym DPM stands for "Dual Path Monitoring".

The project consists of an open-source Python application, a Raspberry Pi SBC (single board computer), a cellular modem and an Eyezon EnvisaLink-4 ("EVL4") IP module that, in combination, deliver *self-DPM* for a Honeywell Vista security system. Consequently, no Central Monitoring Station services are required or included.

#### Which Cellular Modem?

A bewildering variety of cellular modems are available from several, different manufacturers. Initially, it was also unclear which communications provider would ultimately be used. Therefore, the first step was to visit the websites of AT&T, T-Mobile and Verizon (the three largest US carriers) to identify a LTE Cat-1, LTE Cat-M1, or LTE NB-IoT cellular module *already certified* on *all three* carrier's networks. See Appendix A for website links. For the DPM python application to work as designed, the target cellular modem must have *two* ports that process AT commands, which most do.

# **Short Message Service (SMS)**

Not all Internet-of-Things (IoT) service plans provide SMS functionality. The major carriers, (AT&T, T-Mobile and Verizon) have various IoT offerings, some of which do include SMS. Other service providers, for example, Twilio, offer IoT plans with SMS. It is important to read the "fine print" about carrier coverage areas, billing rates per active Subscriber Identification Module (SIM card) and for each SMS sent and received, before deciding which service provider to use. See Appendix A for links to some relevant websites.

# **Complete Kits vs. Individual Components**

Various Raspberry Pi cellular modem hats and even complete IoT project kits are available from vendors such as Waveshare, Sixfab and others – see Appendix A. However, after some research, for this low-budget endeavor, most components were purchased on AliExpress and eBay.

# **Project Hardware**

- EnvisaLink-4 ("EVL4") IP interface module
- Raspberry Pi model 2B with 32GB micro SD card
- Raspberry Pi Hat with mPCIe socket for a cellular modem
- Telit LE910-NA1 mPCIe cellular modem and IoT SIM card
- pair of u.FL to SMA pigtails
- 4G LTE MIMO antenna with 15 ft of coaxial cable and SMA connectors

## **Project Hardware -- Pictures And Notes**

**4G LTE mPCIe Hat** (aliexpress.com ~ \$15 to \$20 in 2022)

**Telit LE910-NA1** (ebay.com, used ~ \$20 in 2022)

4G LTE Base Hat

Size: approx. 8.5x5.5x2.5 cm / 3.3x2.2x1 inch For Raspberry Pi 4, 3, 2, B+, Asus Tinker Board,

Rock 64, ARTIK's Board, LattePanda

Compatible with the following mini PCI-E modules: Quectel: EC25/EC21/ EC20 /UC20/ LTE-EP06

Sierra: AirPrime MC Series

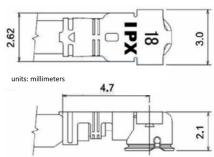

Telit: LM960, LE910V2, HE910, LE910Cx Huawei: ME909s-120, ME909s-821, etc. Simcom: SIM7100, SIM7230, etc.

ZTE: ZM8620, etc. U-Blox: MPCI-L2 Series

Thales: PLS62W, mPLS8, mPLAS9

#### **u.FL-SMA pigtails** (aliexpress.com ~ \$1 each in 2022)

**4G LTE Antenna** (aliexpress.com ~ \$10 to \$15 in 2022)

Note: u.FL connectors come in different sizes!

4G LTE WiFi external panel MIMO antenna 700-2600MHz with coaxial cables of 1 to 5 meter (3 to 15 feet approx.) in length, depending on specific model. Approximately 5 inches x 9 inches x 1 inch.

**EnvisaLink-4 IP module** (various suppliers ~ \$100 in 2022)

Eyezon EnvisaLink-4 ("EVL4"). This IP interface module measures about 4" long by 1.5" wide and has a single RJ45 connector for wired Ethernet connectivity.

It can be purchased at eyezon.com, amazon.com, alarmgrid.com and other online vendors.

### **Preparing the Raspberry Pi**

This project used 32-bit "Buster" with Desktop (debian V10, kernel V5.10) as the operating system. The "lite" version is not recommended because utilities such as File Manager, Geany, Text Editor, Thonny, etc., bundled with the Desktop edition are very useful when initially building, configuring and testing the DPM application.

The 32-bit OS is compatible with all Pi models (<a href="https://www.raspberrypi.com/software/operating-systems">https://www.raspberrypi.com/software/operating-systems</a>), and for this project, the target, previously purchased, Raspberry Pi model 2B only had a 32-bit processor and 1GB of RAM, but that proved to be more than adequate.

Although Pi OS "Bullseye" (debian V11, kernel V5.15) is more current and comes with Python V3.9, it was (as of the publication date of this document) accompanied by a not-yet-patched, linux kernel issue, where /dev/ttyACMO does not function correctly, but must do so, in order for the DPM.py application to work as designed.

### Micro SD Card Plus Raspberry Pi Imager

Purchase (e.g. from amazon.com, newegg.com, or similar) a high quality micro SD card, for example a 32GB Samsung Pro Endurance. Install Raspberry Pi Imager (<a href="https://www.raspberrypi.com/software">https://www.raspberrypi.com/software</a>) on your Windows/MacOS/Ubuntu computer and image Pi OS onto the micro SD card.

## **Pi OS Configuration**

The following instructions assume the computer name of the Raspberry Pi is "raspberrypi" and that the user account name is "pi1". If different, the actual details for *your* Raspberry Pi will need to be substituted accordingly.

This project was successfully developed and tested with the following requisite software components:

- 32-bit Pi OS "Buster" (with Desktop)
- python V3.9.15
- pip V18.1
- pygtail V0.12.0
- pySerial V3.5
- luhn V0.2.0
- telnetlib
   (the python Telnet library is to be deprecated after Python V3.11 <a href="https://peps.python.org/pep-0594/#telnetlib">https://peps.python.org/pep-0594/#telnetlib</a> .
   However, as an insurance policy, a copy of telnetlib source code will be stored with this project.)

| Step | Instructions / Command Line                                                                                                                                                                                                                                                                                       | Comments                                                                                                                                                                                                                                                                                                                      |  |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| 1    | image the micro SD card using Raspberry Pi Imager                                                                                                                                                                                                                                                                 | 32-bit Pi-OS "Buster" release with Desktop                                                                                                                                                                                                                                                                                    |  |
| 2    | Boot the Ras Pi and perform initial configuration including the download and installation of any required software updates.                                                                                                                                                                                       | Ensure there is an Internet connection!                                                                                                                                                                                                                                                                                       |  |
| 3    | sudo raspi-config                                                                                                                                                                                                                                                                                                 | Enable: Boot-to-Desktop, Network-at-Boot and SSH (Secure Shell). Disable: Screen-Blanking, Splash Screen.                                                                                                                                                                                                                     |  |
| 4    | <pre>install Python V3.9.15 cd \$HOME wget https://www.python.org/ftp/python/3.9.15/Python- 3.9.15.tgz tar -xzvf Python-3.9.15.tgz cd Python-3.9.15 ./configureenable-optimizations sudo make altinstall sudo ln -sf /usr/local/bin/python3.9 /usr/bin/python python -V (should respond with Python 3.9.15)</pre> | As of the publication date of this document, using Python V3.10.x was problematic as seemingly, it does not include SSL or TLS and pypi.org requires https for installs, via pip.  The make process for Python 3.9.15 takes about 30 to 45 minutes.  (Note: each of the commands opposite should be entered as a single line) |  |
| 5    | <pre>pip3 -V pip 18.1 from /usr/lib/python3/dist-packages/pip (python 3.7)</pre>                                                                                                                                                                                                                                  | check for pip3 presence and version. We'll use this version (18.1) of pip for the next step.                                                                                                                                                                                                                                  |  |
| 6    | Install Pyserial and Pygtail and luhn                                                                                                                                                                                                                                                                             | "Pyserial" is for serial communications                                                                                                                                                                                                                                                                                       |  |
|      | <pre>sudo pip3 installtarget=/usr/local/lib/python3.9 Pyserial  sudo pip3 installtarget=/usr/local/lib/python3.9 Pygtail  sudo pip3 installtarget=/usr/local/lib/python3.9 luhn</pre>                                                                                                                             | "Pygtail" is for 'tailing' the EVL4's syslog file "luhn" is a check-digit module.  (Note: each of the commands opposite should be entered as a single line)                                                                                                                                                                   |  |
| 7    | cd \$HOME                                                                                                                                                                                                                                                                                                         | create target deployment folders                                                                                                                                                                                                                                                                                              |  |

| 21   | If it is working correctly, congratulate yourself; if not, troubleshoot!                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |  |
| 22   | Optionally, install Putty – can to talk to the cellular modem directly and facilitate trouble shooting. See Appendix B                                                                                                                                                                                                                                                                                                                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |  |
| 23   | After final physical deployment of the Ras Pi into the home security system enclosure, install Putty on your Windows/Linux desktop/notebook computer. Patch into the same network subnet and communicate with the Ras Pi using SSH (secure shell) plus the "pil" account and password. This will facilitate making any final changes to the DPM.ini configuration file and/or perusing log files.  In the <i>example</i> shown to the right, the IP V4 address of the Raspberry Pi is 192.168.80.4 | Putty Configuration ? ### **Physical Installation**

In many home security systems, the control unit is housed in a sturdy metal enclosure with a lockable door, as illustrated by the Honeywell Vista-20P starter-kit, on the right.

When zone-expansion modules are inside the cabinet, along with wiring and a "backup" battery, there may be little or no free space. If so, this Ras Pi project could be deployed in a small (approx. 5 inch x 3 inch x 2 inch) or larger, ventilated, plastic box, attached to the exterior of the main cabinet.

For better overall security, an additional empty, lockable enclosure can be procured, (Google search "Honeywell Vista enclosure only") to accommodate the Ras Pi and associated networking gear and subsequently connected by a data cable to the main box. To avoid electrical faults and/or short circuits, the Ras Pi must be mounted using plastic *standoffs* (a.k.a. "offsets", or "legs"), or against a layer of non-conductive material (e.g. plastic), *not* directly against the metal case.

Ideally, the security system should have it's own network sub-net (e.g. 192.168.nnn.nnn), supported by a small (e.g. 4-port) router, with appropriate firewall rules in effect, connected to an Internet Gateway. Use DHCP with MAC to IP address mappings, to assign consistent IP addresses to the Ras Pi and EVL4.

Wired Ethernet (e.g. Cat-5 cable) to the Internet Gateway is the more robust, reliable and secure way to establish connectivity, not least because "wireless anything" does not work well inside a metal security cabinet and external antennas are then required.

A small, pre-owned, non-WiFi router (e.g. from ebay.com) will be fine for this purpose. WiFi routers typically have some RJ45 ports for Ethernet cable connections and their WiFi can usually be turned off via the router's software configuration program, as desired. Regardless, first verify dimensions to ensure it will fit inside the cabinet, if that's to be it's final location.

# **Power Supply**

Using a higher current (approx 5 amp, USB-style) 5V DC power supply to drive the Raspberry Pi facilitates powering the Pi Hat *and* cellular modem from a USB port on the Raspberry Pi itself. The overall system will be less likely to experience "low voltage" events on the infrequent occasions when greater current is pulled. With this configuration, when the Ras Pi is rebooted, the hat is power-cycled and therefore, so is the cellular modem. The modem has its own CPU or MCU and firmware, so rebooting daily will help reduce problems due to memory leaks and similar ailments.

Depending upon the position of the slide-switch, the hat used for this project can power the cellular modem from an independent 5V DC feed. Setting "ModemSoftReboot = True" in the DPM.ini configuration file will cause the modem to be soft-rebooted by the startup.py process, as invoked by the Housekeeping script (DPM.sh). Similarly, setting "Televl4SoftReboot = True" in the DPM.ini configuration file will cause the EVL4 IP interface module to be soft-rebooted.

|                                                                                        |                                                                                                              |
|                                                                                        |                                                                                                              |
|                                                                                        |                                                                                                              |
|                                                                                        |                                                                                                              |

### Appendix B: Ras Pi Filesystem Folders, Pi OS Changes, Etc.

Cellular modems are complex devices. To avoid being trapped in an information desert, ensure you obtain a copy of the technical documentation, especially, the "AT" command set, for a cellular modem *before* actually purchasing it!

Modem Manager ("mmcli") is a useful testing tool that can provide some, albeit limited, insights about a given cellular modem. Putty can also be used to communicate directly with serial devices.

Cellular modem modules present themselves as different devices depending on operating systems (linux, windows, etc) and the specific device driver being used. For the Telit modem used in this project, ACM0 and ACM3 are serial ports, that process "AT" commands.

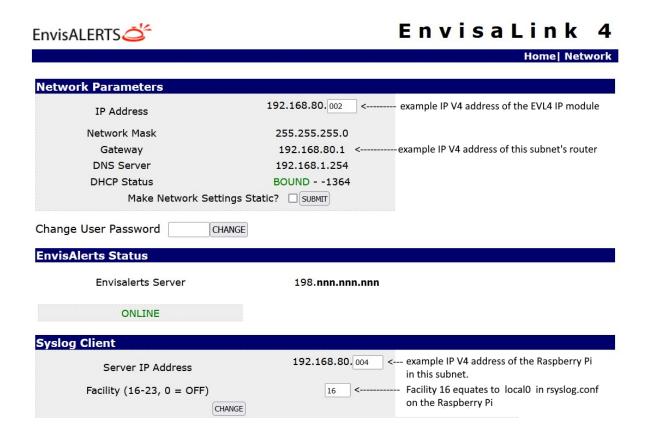

```
pil@raspberrypi: $ ls -l /dev/ttyACM*
crw-rw---- 1 root dialout 166, 0 mmm dd hh:mm ttyACM0
crw-rw---- 1 root dialout 166, 1 mmm dd hh:mm ttyACM1
crw-rw--- 1 root dialout 166, 2 mmm dd hh:mm ttyACM2
crw-rw--- 1 root dialout 166, 3 mmm dd hh:mm ttyACM3
crw-rw--- 1 root dialout 166, 4 mmm dd hh:mm ttyACM4 crw-rw--- 1 root dialout 166, 5 mmm dd hh:mm ttyACM5
The (default) user "pi1" should be added to the "dialout" group to avoid having to run
processes accessing the cellular modem as "root": sudo usermod -a -G dialout pil
pil@raspberrypi: $ grep pil /etc/group | grep -v grep
adm:x:4:pi1
dialout:x:20:pi1
cdrom:x:24:pi1
sudo:x:27:pi1
audio:x:29:pulse,pi1
blah ... blah ... blah
For a Raspberry Pi with the default computer name ("raspberrypi") and default user name
("pi1"), home looks like this:
pi1@raspberrypi:~ $ cd $HOME
pil@raspberrypi:~ $ pwd
/home/pil
The default folders beneath home are shown below. The new folder "DPM-EVL4" was created
to accommodate the python application components and its operational log files. The date
and time stamps have been generalized here for convenience.
drwxr-xr-x 2 pil pil 4096 mmm dd hh:mm Bookshelf
drwxr-xr-x 2 pil pil 4096 mmm dd hh:mm Desktop

#### EVL4's Web-browser Interface To Configure Syslogging

Open an internet browser (Chrome/Firefox/Edge), enter the IP V4 address of the EVL4 module (192.168.80.2 in this example) and then log into the EVL4 with the credentials "user" and the EVL4's *cleartext* password.

#### Examples of Putty talking to cellular modem serial ports

```

### **Appendix G: Sending SMS Messages To DPM**

The DPM application can process two types of *inbound* SMS messages, namely an Arm request (e.g. "Arm partition 1 away") and a system Status request (e.g. "Status?"), providing, in the DPM.ini configuration file, "ModemInboundSMS = True" and "InboundSMSCellPhones" is populated with at least one valid cell phone number. Since SMS traffic is not encrypted, a *disarm* request is **not** supported.

For security reasons, an "arm only" user account should be created on the Honeywell Vista system for each user (i.e. cell phone). The following key sequences should be entered on a Honeywell keypad:

```
MasterCode + 8 + uu + ssss
      where uu is the new user's number and ssss is their security code
MasterCode + 8 + uu + # 1 + 1
      where uu is user's number and 1 means ARM only
```

To find the security code (ssss) for each cell phone number, run the DPM application in DEBUG mode, send a "Arm partition 1 away" request, via SMS (it will fail until the security system has been configured) to the wireless modem's phone number and then look in DPM's log file for:

TEL-014I Submitting Process Keystrokes request ^03,1\$ssssnn

#### SECURITY CODES Your installer assigned a master code that is used to perform all system functions In addition, other security codes can be assigned for use by other users. Only the System Master and Partition Master can assign security codes to users. Users are identified by 2-digit user numbers. Only the System Master can change user partitions. • In addition to a security code, each user is assigned an authority level and various system attributes. See the full User Guide for definitions of each Authority Level. Security codes can be used interchangeably within a partition when performing system functions (a system armed with one security code can be disarmed by a different security

- code), with the exception of the Guest and Arm Only codes. Security code programming involves these steps: 1. Choose a user number from the set of users assigned to the partition in which the user will be operating, and assign a 4-digit security code. 2. Assign an authority level to that user.
- 3. Assign other attributes as necessary

#### **Assigning Security Codes and User Attributes**

The following lists the various command strings for adding security codes and attributes. NOTE: Partition Master codes (VISTA-20P Series only) apply only to those user numbers previously assigned (by the system master/installer) to the partition master's partition.

| Function                     | Commands                                                                                                                                                                                                                                                  |  |  |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|
| Change System<br>Master Code | System Master code + 8 + [02] + new code + new code again                                                                                                                                                                                                 |  |  |
| Add Security Code            | Master code + 8 + user no. + new user's security code The Keypad beeps once to confirm that new user was added.                                                                                                                                           |  |  |
|                              | Master code + 8 + [user no.] + # 0                                                                                                                                                                                                                        |  |  |
| Delete Security<br>Code      | The security code and all attributes* set for this user number, including any associated RF keys, are erased from the system. (*except assigned partition)                                                                                                |  |  |
| Authority Level              | Master code + 8 + [user no.] + # 1 + auth. level Authority Levels: 0 = standard user 1 = arm only 2 = guest 3 = duress 4 = partition master (VISTA-20P Series only)                                                                                       |  |  |
| Access Group                 | Master Code + 8 + [user no.] + 8 2 + group (1-8) You can assign users to a group, then set an access schedule that defines the times this group of users can operate the system. The system ignores these users outside the scheduled times.              |  |  |
|                              | System Master Code $+$ $\boxed{8}$ $+$ [user no.] $+$ $\boxed{#}$ $\boxed{3}$ $+$ $\boxed{0}$ $+$ part. $+$ $\boxed{#}$ This assigns the partitions the user can access. If more than one, enter partition numbers sequentially, then press $[#]$ to end. |  |  |
| User's Partition             | E.g., master code + [8] + [user no.] + [#] [3] + [0] + [1] [2] + [#] gives the user access to partitions 1 and 2 and common partition.                                                                                                                    |  |  |
|                              | Partition Entries: 1 = partition 1 and common 2 = partition 2 and common 3 = common partition only                                                                                                                                                        |  |  |

# Appendix H: Sample Usage of protectPassword.py On a Raspberry Pi SBC

python protectPassword.py

Enter your password (minimum of 8 characters): YOURPASS

Your stupefied password is: 'n637B\x08JX' (including the encapsulating single quotation marks!) ... now copy and paste it into its target destination.

As a final check, you entered: YOURPASS as your cleartext password

# **Appendix I: Document History**
